

CASE STUDY

AI in Manufacturing IOP Supply Chain

Innovacio unified 6 fragmented data streams—SKU master data, inventory, purchase orders, supplier records, shipment updates, and sales history—into 1 AI control tower for demand forecasting, raw-material planning, real-time freight visibility, and faster cross-functional decisions.

Problem

The client's operations were running on disconnected Excel files, manual updates, and fragmented department-level reporting. Data existed across procurement, logistics, inventory, and sales, but it was not standardized, validated, or connected in a way that allowed teams to make fast decisions.

Procurement teams lacked a reliable view of raw material demand, supplier timing, and future purchasing needs. Logistics teams had limited live visibility into ocean freight, truck movement, booking progress, and shipment arrival timelines. Leadership had no single operational view that brought these functions together in a clear, actionable format.

The existing ERP environment, including legacy systems such as Syspro, contained valuable historical data, but it was difficult to use for forecasting or planning because the information was inconsistent, delayed, and spread across multiple processes.

How we solved it

- Innovacio designed and delivered an AI-powered Integrated Operations Platform that transformed fragmented legacy information into a clean, centralized operational system.
- We first created a structured data foundation that unified SKU master data, inventory records, purchase orders, supplier information, shipment updates, and sales history into a single governed environment. This gave the organization one trusted source of truth across departments.
- On top of this clean data layer, we built AI forecasting models to support both **demand forecasting** and **raw material forecasting**. These models helped procurement teams anticipate future needs, reduce guesswork, and improve purchasing decisions based on historical demand patterns, seasonality, and operational trends.
- For logistics, we developed a live dashboard layer that provided end-to-end visibility into **ocean freight, truck tracking, booking status, PO movement, and arrival management**. Teams could monitor shipment progress in real time, spot delays early, and coordinate faster across vendors, warehouses, and internal departments.
- We also created operational dashboards for sales planning, top-SKU analysis, revenue visibility, and quality monitoring so leadership could see the business from one command center instead of several disconnected reports.

Impact

The platform gave the client a clear and unified operational view across supply chain, procurement, logistics, quality, and planning.

Legacy spreadsheets were replaced with live dashboards that improved visibility and reduced manual reporting effort. Procurement teams gained better confidence in raw material planning and were able to align purchasing with forecasted demand. Logistics teams received a real-time control tower for shipments, trucks, and ocean freight movement. Leadership gained faster access to performance insights, exceptions, and operational risks.

As a result, the organization moved from reactive decision-making to a more proactive and data-driven operating model.

Operational Clarity Unified legacy data into one clean command center with reliable visibility across departments.	Faster Planning Enabled AI-based raw material forecasting and better purchase planning from historical and operational data.
Better Logistics Control Provided real-time tracking for ocean freight, trucks, bookings, POs, and shipment arrivals.	Quality Improvement Supported proactive quality management and helped reduce scrap through connected data.

Data Management Improvement

Innovacio cleaned and organized historical business data so the client could finally use legacy records for planning instead of relying on manual interpretation. By standardizing SKU structures, consolidating procurement records, and connecting inventory and sales data, the platform improved data clarity across the full operation.

Procurement Forecasting

The AI layer helped procurement teams forecast raw material demand based on sales trends, production needs, and SKU movement. This reduced overbuying, improved supplier planning, and gave the team a more reliable basis for purchase decisions.

Logistics Visibility

The logistics dashboard gave the client live access to freight movement across both ocean and ground transport. Teams could monitor shipments from booking to arrival, track delays earlier, and manage exceptions before they affected operations.

Executive Visibility

Leadership no longer had to depend on separate reports from different departments. The command center gave them a shared view of supply chain status, financial indicators, logistics movement, and quality issues in one place.

Final Takeaway:

By replacing disconnected spreadsheets with a customized AI-powered integrated platform, the client gained a single operational view across supply chain, logistics, quality, and planning. The result was a more connected, proactive, and scalable operating model designed to keep every department aligned and ahead of what is coming next.
